In a war against NATO, Backfires were to pound Western ports and airfields.

The Tu-22M Backfire bomber was developed in the 1960s as a supersonic, variable-sweep-wing bomber for the Soviet air forces and Navy. Equally capable as a strategic bomber or naval strike platform, the Tupolev aircraft provided the power to strike naval targets on the Soviet periphery or, given the right equipment, targets at intercontinental range. Its primary mission in a war against NATO was to cut US supply lines to Europe by destroying strategic harbors and airfields. Russia inherited the Soviet inventory.

Backfire’s advanced wings were key to the project. They were variable in sweep and tapered with curved tips. When extended, they permitted relatively short takeoff and landing. Swept, they provided efficient cruising, high top speed, and stable high-speed, low-level flight. The long and slender fuselage and pointed nose gave it a rakish look. Its low-level penetration features made it more survivable than its predecessors.

Upgrades gave the basic airplane stronger engines, better avionics, and more ordnance—including supersonic missiles. It could accept air-refueling probes to increase range, a fact that became a major issue in US-Soviet SALT II negotiations.

In the 1980s, Backfires were employed in conventional bombing raids in Afghanistan, particularly during the last year of direct Soviet involvement. Russian pilots flew some 100 operational sorties against rebels in Chechnya in the mid-1990s and against Georgian forces in the 2008 South Ossetian War. It was in the latter conflict that the first Backfire was lost in combat, shot down by a Georgian missile. In the 2000s, Russian Backfires resumed combat patrols in international airspace.
